

Fundamentals of Performance Tuning for Python Applications

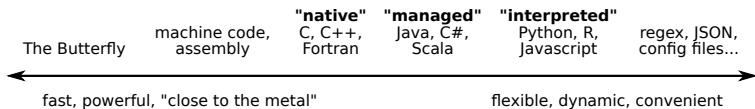

Alexey Svyatkovskiy

October 25, 2016

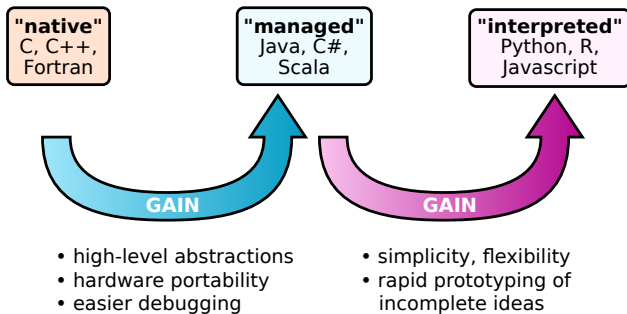

Outline

1. Programming languages
2. Ways to boost the performance of Python applications
3. Hands-on exercises

What happens in the compilation step?

- ▶ Whole program is interpreted and turned into machine instructions (possibly for a virtual machine).
- ▶ All variables are interpreted as belonging to specific types: `int`, `string`, `MissileController`...
- ▶ Uses of these variables are checked for validity:
 - ▶ can't pass a `MissileController` into the `cosine` function;
 - ▶ can't call `launchAllMissiles()` on a `string`.

Interpreted languages do none of these things; you find out about misuses of variables at runtime (can be good, can be bad).

Python

- ▶ Powerful built-ins
- ▶ Object oriented
- ▶ Rich libraries
- ▶ Dynamic typing

There are two slightly inconsistent versions of python in the wild, python 2.x and python 3.x Within the 2.x series (currently 2.7.12) features were added from time to time. Eventually we'll all have to move to python 3 (currently at 3.5).

Purpose of the course

- ▶ Discuss fundamentals of performance tuning for Python applications
- ▶ Learning how to use tools like Numpy, Cython, Tensorflow
- ▶ Leverage techniques like using generators and sorting keys,
- ▶ Interface Python with compiled code with Ctypes
- ▶ Parallelizing code with Multiprocessing and Joblib libraries
- ▶ In addition, it discuss how to take advantage of Princeton University computing resources

Role of computing in Science and Engineering

Computation has joined experiment and theory to become the third component of science. Nowadays, even social scientist need computing resources to carry out their research and extract meaningful insights.

Three stages of scientific computing might be identified as:

- ▶ model building: produces equations
- ▶ simulation/experiment: produces data
- ▶ analysis and visualization

Performance tuning is essential to achieve accurate results in a timely manner.

Python development environments

For this course, we will use Jupyter notebook and occasionally I will resort to the command line and vim text editor.

You can refer to the following wikipedia entry to learn about various development environments you can use with Python:

http://en.wikipedia.org/wiki/Integrated_development_environment. An integrated development environment (IDE) includes language-aware editors, compilers/interpreters, build systems, debuggers, etc.

- ▶ IDLE is an example of a Python-specific IDE.
- ▶ Microsoft Visual Studio and Xcode (for OS X) each support several programming languages.
- ▶ The best examples of multi-language cross-platform IDEs are Eclipse and Netbeans, though the latter does not currently support Python.

Interpreted language

An **interpreted language** is a [programming language](#) for which most of its implementations execute instructions directly, without previously compiling the sequence of one or more [subroutines](#) already compiled into machine code.

The terms *interpreted language* and *compiled language* are not well defined because, in theory, any programming language can be either interpreted or compiled.

Interpreted languages can also be contrasted with [machine languages](#). Functionally, both execution and interpretation mean the same thing – code in form and has an [assembler](#) representation, the term "interpreted" is practically reserved for "software processed" languages (by [virtu](#)al machines).

In principle, programs in many languages may be [compiled](#) or interpreted, emulated or executed natively, so this designation is applied solely to those languages that are typically interpreted.

Many languages have been implemented using both compilers and interpreters, including [BASIC](#), [C](#), [Lisp](#), [Pascal](#), and [Python](#). [Java](#) and [C#](#) are also interpreted languages.

Historical background [[edit](#)]

In the early days of computing, language design was heavily influenced by the decision to use compiling or interpreting as a mode of execution. The decision was often made for other reasons, such as the availability of hardware or the need for portability.

Initially, interpreted languages were compiled line-by-line; that is, each line was compiled as it was about to be executed, and if a loop or subroutine was encountered, the entire program was recompiled. This method was slow, but it allowed for easy debugging and modification. Modern so-called interpreted languages use an [intermediate representation](#), which combines compiling and interpreting.

NumPy

Why numpy arrays can accelerate your applications?

- ▶ A NumPy ndarray array is described by number of dimensions, shape, data type, and the actual data stored in it. The data is stored in a homogeneous and contiguous blocks of memory, at a particular address in system memory RAM
- ▶ Spatial locality in memory access patterns results in significant performance gains, notably thanks to the CPU cache.
- ▶ Data elements are stored contiguously in memory, so that NumPy can take advantage of vectorized instructions on modern CPUs, like Intel's SSE and AVX, AMD's XOP
- ▶ NumPy can be linked to highly optimized linear algebra libraries like BLAS and LAPACK, for example through the Intel Math Kernel Library (MKL).
- ▶ Storing data in a contiguous blocks of memory ensures that the architecture of modern CPUs is used optimally, in terms of memory access patterns, CPU cache, and vectorized instructions

Cython

Cython

What is TensorFlow?

- ▶ Open source Machine Learning library
- ▶ Especially useful for Deep Learning
- ▶ For research and industry
- ▶ Apache 2.0 license

Data Flow graphs

Computation is defined as a directed acyclic graph (DAG) to optimize an objective function

- ▶ Graph is defined in high-level language (Python, C++, go)
- ▶ Graph is compiled and optimized
- ▶ Graph is executed (in parts or fully) on available low level devices (CPU, GPU)
- ▶ Data (tensors) flow through the graph
- ▶ TensorFlow can compute gradients automatically
